

# SQ 6

#1 The SM is a diketone + base is a reactant. This suggests aldol condensation.

an enolate

aldol condensations lead to  $\beta$ -hydroxy aldehydes or ketones which can be dehydrated in a 2nd step to give  $\alpha,\beta$ -unsaturated aldehydes or ketones

up to here, aldol condensation

A

an enolate

E1cB  
an elimination

SQ 6

# 2

this is a mixture of an aldol & Claisen condensation

Now that we are getting more comfortable w/ mechanisms (?), let's work on details:

- show lone pairs on all atoms that are reacting
- show at least 1 typical resonance form when res forms are relevant (i.e. explain reactivity)
- be sure all formal charges are clearly shown
- be sure that each step is balanced — show the little pieces that come off

SA 6

#3 very much like #2, but ...

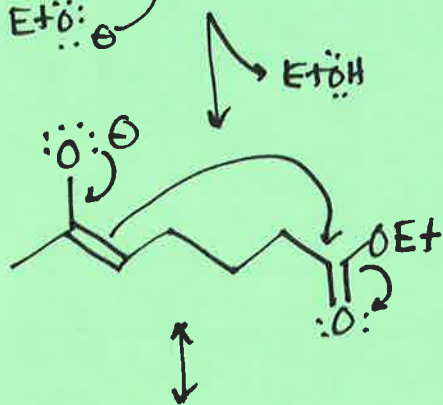

enolates can be made at any of the red arrows. however, the ketone is more acidic & thus favored. but that still leaves 2 options

option A gives a 5-membered ring.  
option B gives a 7-membered ring.

Generally, 5 or 6 membered rings form easily. 3 or 4 membered rings are disfavored due to ring strain. 7+ rings are disfavored due to entropy.

SQ 6

#4

SM is a diester & 1st product is  $\beta$ -ketoester so this first step is a Claisen condensation

5-membered ring  
(but we also know that from the product which is given)

tetrahedral intermediate

tetrahedral intermediate

strong base

decarboxylation occurs due to unique 6-membered ring that puts things in proximity

keto form

enol form

tautomerization

whoa! strap in! buckle up!

H<sub>2</sub>O

+ EtOH

D

SQ6

#5

1st part is like the 1st part of 4 but w/ a larger ring.

$\alpha, \beta$ -unsat. ketone  
Michael or Conjugate  
or 1,4-addn

Bonus Fun!  
What happens to  
this structure if you  
use NaOH instead  
of EtONa?

See problem 4  
for an idea.  
Show the final product.

#5 cont

an enolate,  
different from the  
previous enolate

E1cb

G

IR shows an ester (1740  $\text{cm}^{-1}$ )  
& a conjugated ketone (1700  $\text{cm}^{-1}$ )
